Ans. the Q. No: 1

(a)

The LCS of "RAHMANI" and "JAHANGIR" is,

		J	A	H	A	N	G	I	R
		0	0	0	0	0	0	0	0
R		0	↑0	↑0	↑0	↑0	↑0	↑0	↖1
A		0	↑0	↖1	←1	↖1	←1	←1	↑1
H		0	↑0	↑1	↖2	←2	←2	←2	←2
M		0	↑0	↑1	↑2	↑2	↑2	↑2	↑2
A		0	↑0	↖1	↑2	↖3	←3	←3	←3
N		0	↑0	↑1	↑2	↑3	↖4	←4	←4
I		0	↑0	↑1	↑2	↑3	↑4	↑4	↖5
									←5

we can see that the LCS is →

"AHANI"

Here,

We have two strings,

Let, $X = \{R, A, H, M, A, N, I\}$

and $Y = \{J, A, H, A, N, G, I, R\}$

First compare 'I' and 'R'. If

they matched, find the subsequence
in the remaining string and
then append the 'I' with it

If "I" or, $x_7 \neq y_8$ ("R")

(i) Remove x_7 from X and

find LCS from x_1 to x_{7-1}

and y_1 to y_8

(ii) Remove y_8 from Y and bind
LCS from x_1 to x_7 and
 y_1 to y_{8-1}

In each step, we reduce the size
of the problem into the subproblems.
It is optimal substructure.

It is a dynamic programming approach
because it has optimal substructure.

Ans. the Q. NO: 2, 1

(b)

7 - Queen Problem —

Insert ^a Queen ~~is~~ at Row - 1.

Insert a Queen at Row - 2

Insert a queen into Row 3 and

Insert a queen into Row 5

when we insert a queen in
 Row-5, we see we can't
 insert a queen into row-6,
 so ~~we~~ backtracking

Now,

	1	2	3	4	5	6	7
1	Q						
2			Q				
3					Q		
4		Q					
5							
6							
7							

Again backtracking,

	1	2	3	4	5	6	7
1	Q						
2			Q				
3					Q		
4							Q
5							
6							
7							

So, we insert a queen at Row-5

	1	2	3	4	5	6	7
1	Q						
2			Q				
3					Q		
4							Q
5		Q					
6							
7							

Again, insert a queen into Row-6

	1	2	3	4	5	6	7
1	Q						
2			Q				
3					Q		
4							Q
5		Q					
6				Q			
7							

And Finally,

	1	2	3	4	5	6	7
1	Q						
2			Q				
3					Q		
4							Q
5		Q					
6				Q			
7						Q	

So, the Output : $(1, 3, 5, 7, 2, 4, 6)$

(Ans.)

Ans. the Q. No : 1

(c)

Step - 1

O_i	P	Q	R	S	T	U	V	W	X
P_i	5	46	15	10	20	10	55	12.6	32
W_i	1	10	2	2	3.6	1.2	5.6	7	4
$w_i = \frac{P_i}{W_i}$	5	4.6	7.5	5	5.6	8.3	9.8	1.8	8

1 : 071.0.011.000

(0)

Step - 2

O_i	V	U	X	R	T	P	S	Q	W		
P_i	55	10	32	15	20	5	10	46	12.6		
W_i	5.6	1.2	4	2	3.6	1	2	10	2		
$u_i = \frac{P_i}{W_i}$	9.8	8.3	8	7.5	5.6	5	5	4.6	1.8		
$x_i(1)$	0	0	0	0	0	0	0	0	0		
$x_i(2)$	1	0	0	0	0	0	0	0	0		
$x_i(3)$	1	1	0	0	0	0	0	0	0		
$x_i(4)$	1	1	1	0	0	0	0	0	0		
$x_i(5)$	1	1	1	1	0	0	0	0	0		
$x_i(6)$	1	1	1	1	1	0	0	0	0		
$x_i(7)$	1	1	1	1	1	1	0	0	0		
$x_i(8)$	1	1	1	1	1	1	1	0	0		
$x_i(9)$	1	1	1	1	1	1	1	0.66	0		
$x_i(10)$	1	1	1	1	1	1	1	0.66	0		

Total capacity,

$$m = 26$$

Rest capacity,

$$\rightarrow U = 26 - 0 = 26$$

$$\rightarrow U = 26 - 5.6 = 20.4$$

$$\rightarrow U = 20.4 - 1.2 = 19.2$$

$$\rightarrow U = 19.2 - 4 = 15.2$$

$$\rightarrow U = 15.2 - 2 = 13.2$$

$$\rightarrow U = 13.2 - 3.6 = 9.6$$

$$\rightarrow U = 9.6 - 1 = 8.6$$

$$\rightarrow U = 8.6 - 2 = 6.6$$

$$\rightarrow U = 6.6 - (10 \times \frac{6.6}{10})$$

$$= 0$$

$$\text{Maximum Profit} = \sum p_i x_i$$

$$= (55 \times 1) + (10 \times 1) + (32 \times 1) + (15 \times 1) \\ + (20 \times 1) + (5 \times 1) + (10 \times 1) + (4.6 \times 0.66) \\ = 177.4$$

$$\text{Total weight} = \sum w_i x_i$$

$$= (5.6 \times 1) + (1.2 \times 1) + (4 \times 1) + \\ (2 \times 1) + (3.6 \times 1) + (1 \times 1) + \\ (2 \times 1) + (10 \times 0.66) \\ = 26$$

Fraction taken of the items:

$$(x_P, x_Q, x_R, x_S, x_T, x_U, x_V, x_W, x_X) \\ = (1, 0.66, 1, 1, 1, 1, 1, 1, 0, 1)$$

(Ans.)

If we're not allowed to take fraction of an object, then it turns into dynamic problem rather than greedy problem. It is called "0-1" knapsack.

Then, we need to find an optimal substructure to find the global optimal solution, rather than a greedy technique to solve the problem.

Ans. the. Q. No: 1

(d)

Backtracking is ^{usually} a recursive approach to enumerate all possible solutions. Whenever a dead-end is encountered, the algorithm backs up and systematically tries to find a different solution.

There are greedy algorithms that are guaranteed to find a ~~different~~ solution. There are the globally optimal result, but there are also greedy algorithms which will only find suboptimal results.

Dynamic Programming and Greedy
mostly solves optimizations
problem, better.

That's why some problems
like, N-Queen problem, is
much more efficient to solve
with backtracking other
than Greedy or DP.

Ans. the Q. NO: 2

(a)

Given,

$$Q = 25,000$$

$$R = 68000$$

$$S = 3000$$

$$T = 13000$$

$$U = 1000$$

$$V = 76000$$

$$W = 15000,$$

$$X = 5000$$

$$Y = 18000$$

$$Z = 26000$$

Now, Let, $U = 1, S = 3, X = 5,$

$T = 13, W = 15, Y = 18, Q = 25, Z = 26,$

$R = 68.$ and $V = 76$

Step - 1 :

U:1

S:3

X:5

T:13

W:15

Y:18

Q:25

Z:26

R:68

V:76

Step - 2 :

X:5

T:13

W:15

Y:18

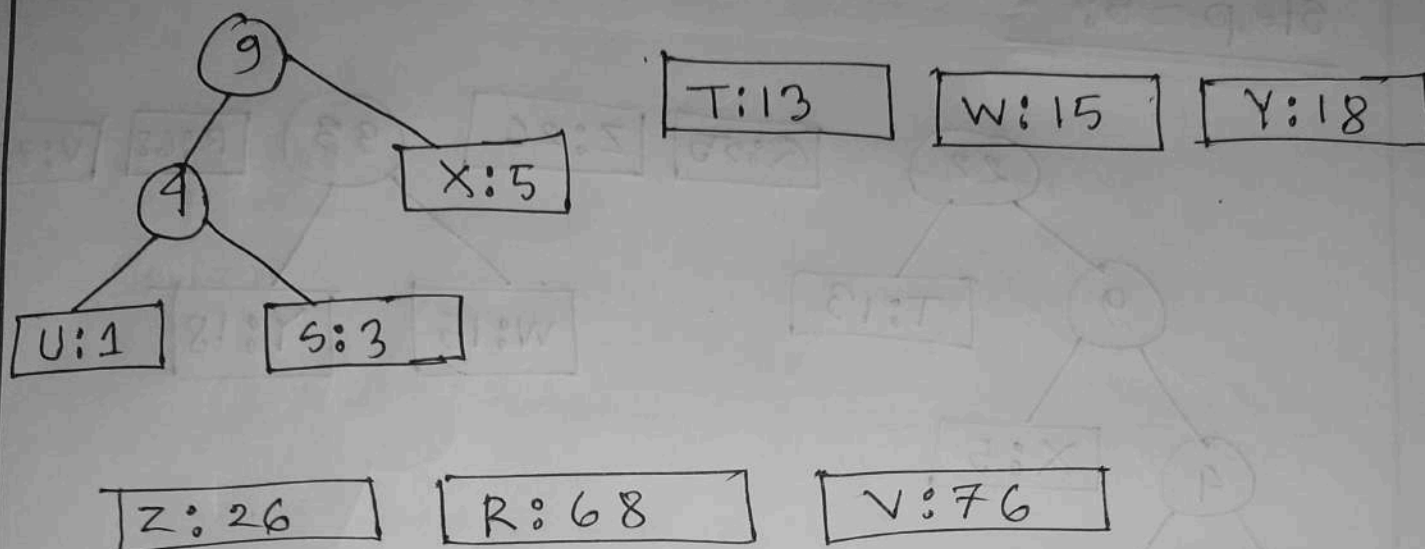

Q:25

Z:26

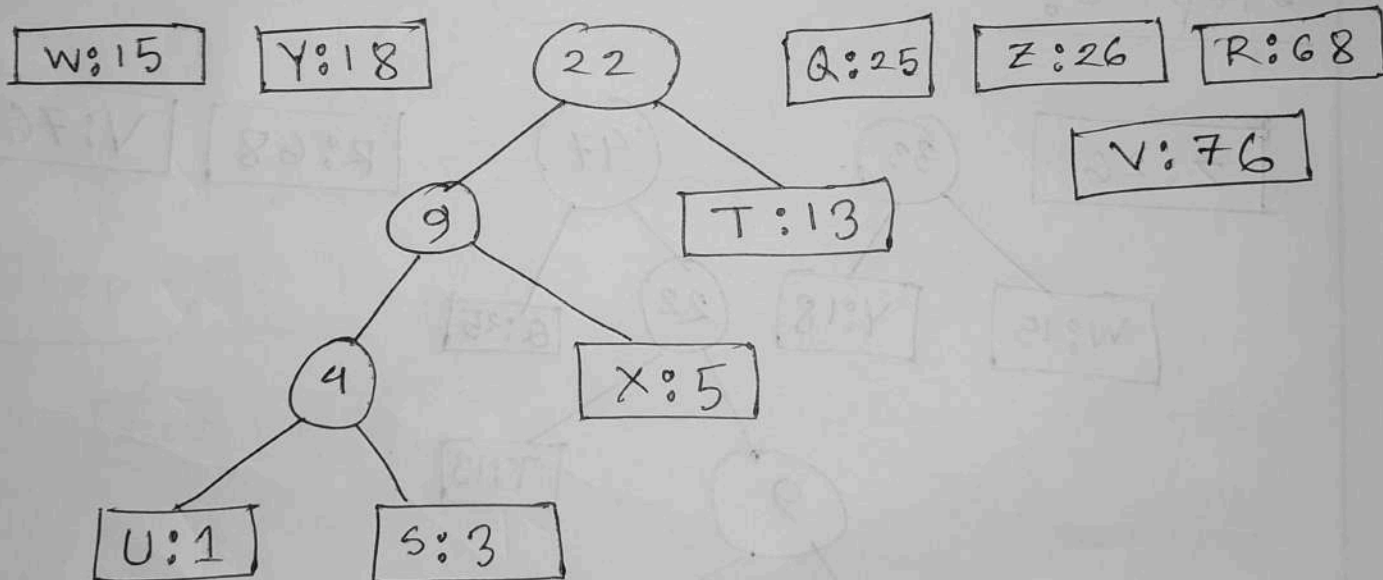

R:68

V:76

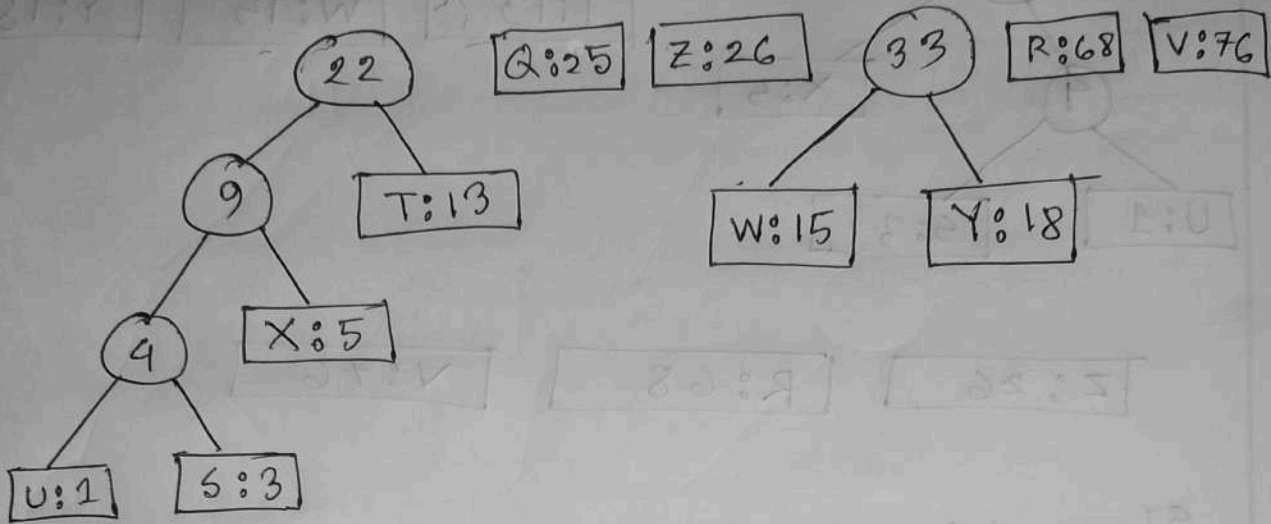

Step - 3 :

Step-4:

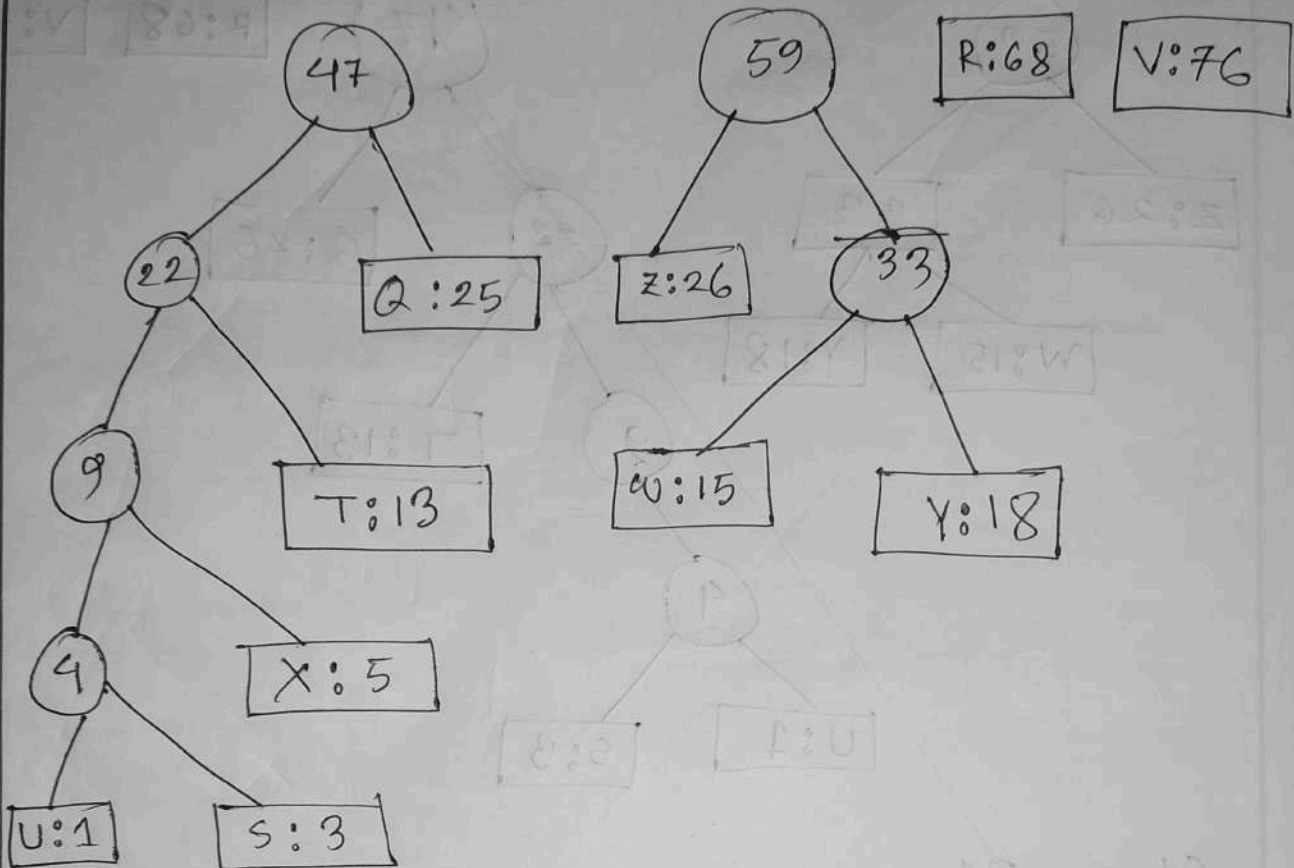

Step - 5:

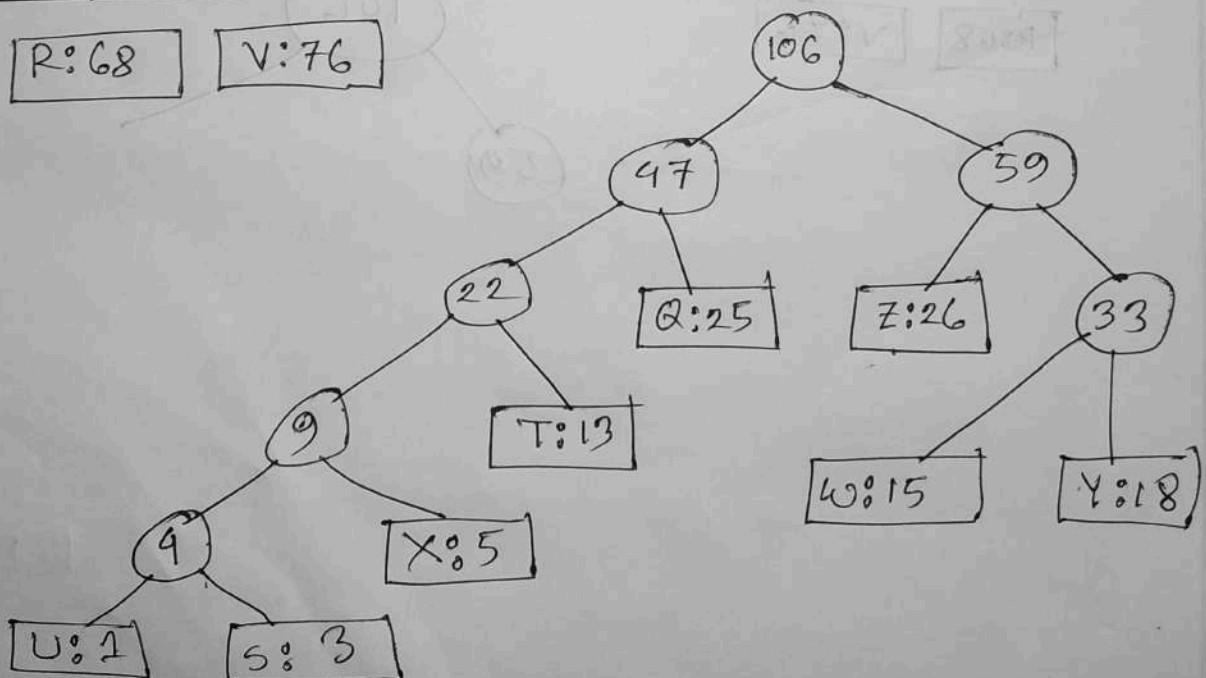

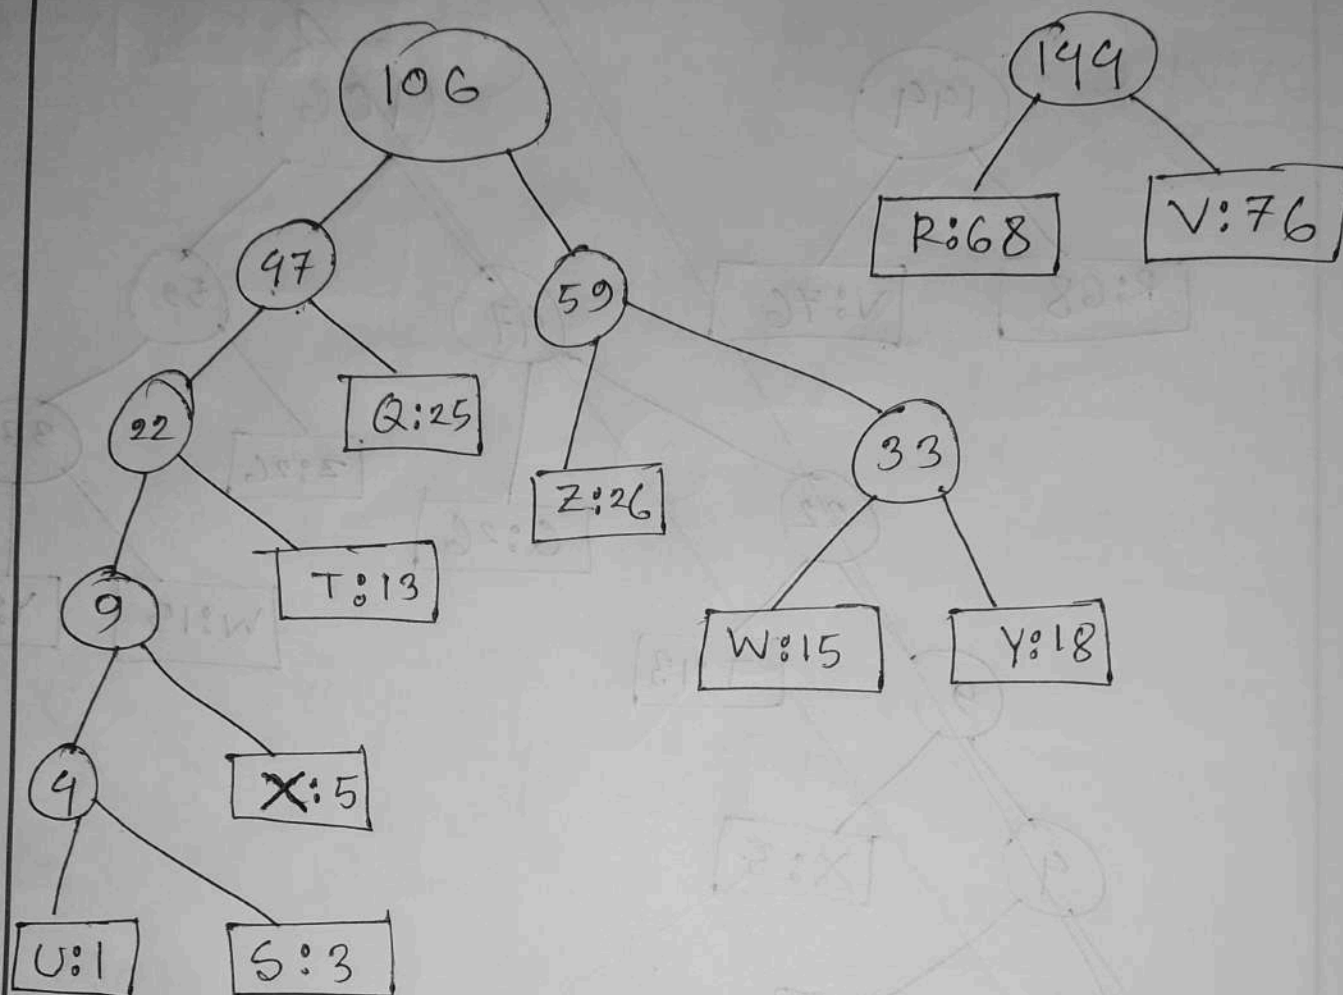

Step - 6:

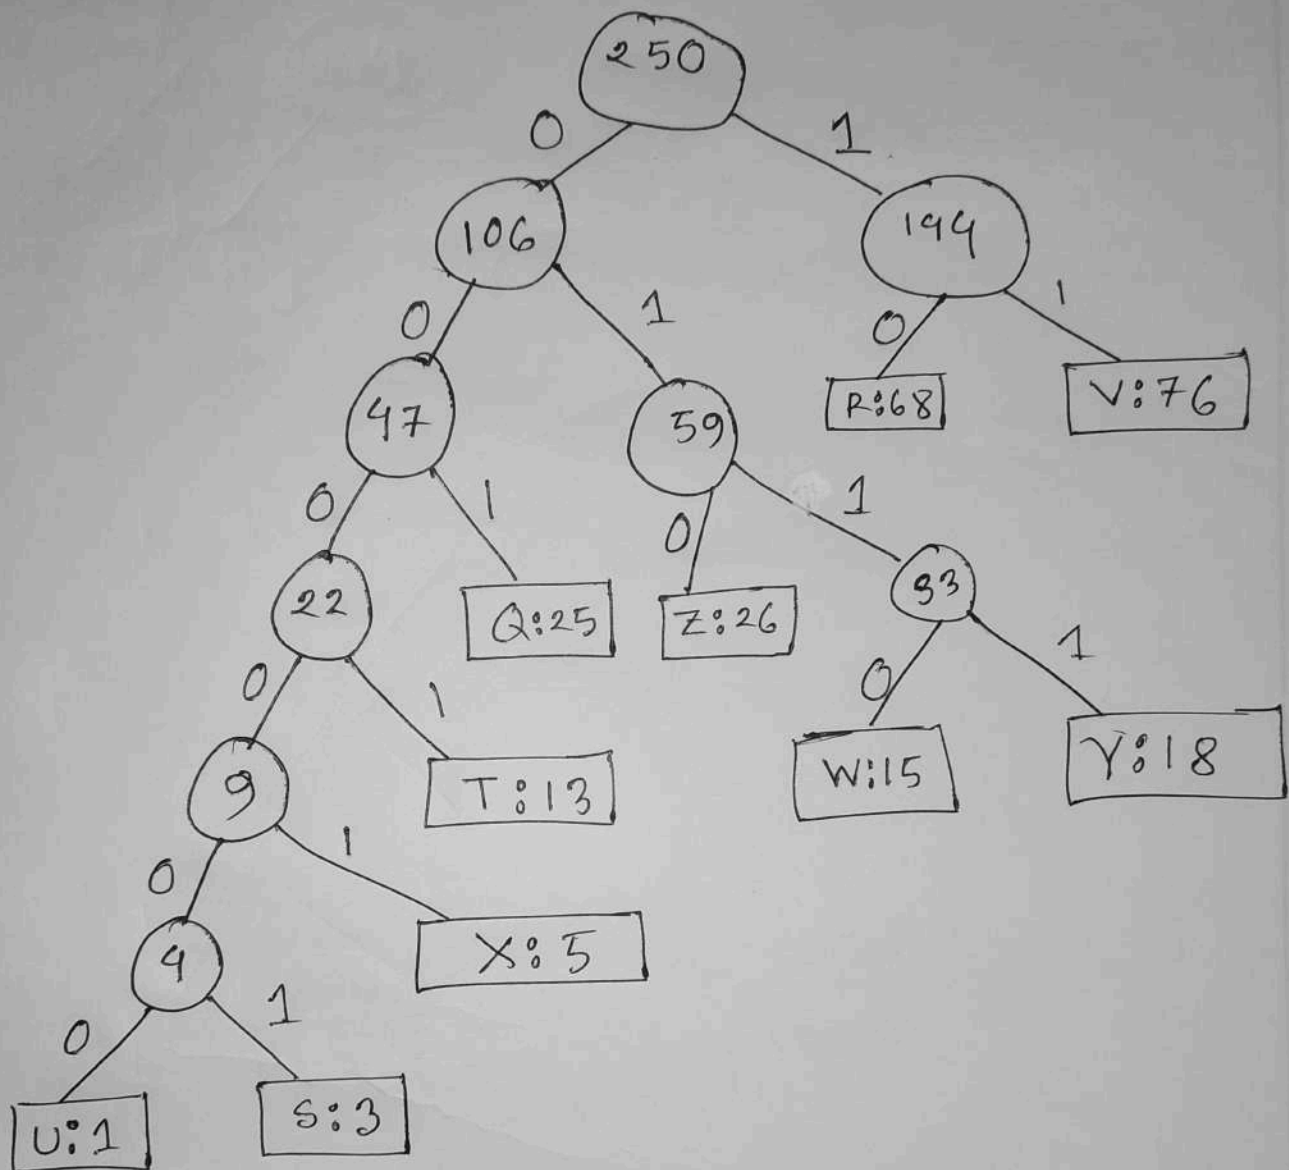

Step-7:Step-8:

R:68 V:76

Step-9 :

P.T.O

Step-10:

The Huffman codes are:

R = 10, V = 11, Z = 010, Q = 001

T = 0001, W = 0110, Y = 0111,

X = 00001, U = 000000 and

S = 000001

Ans. the Q. NO : 2

(b)

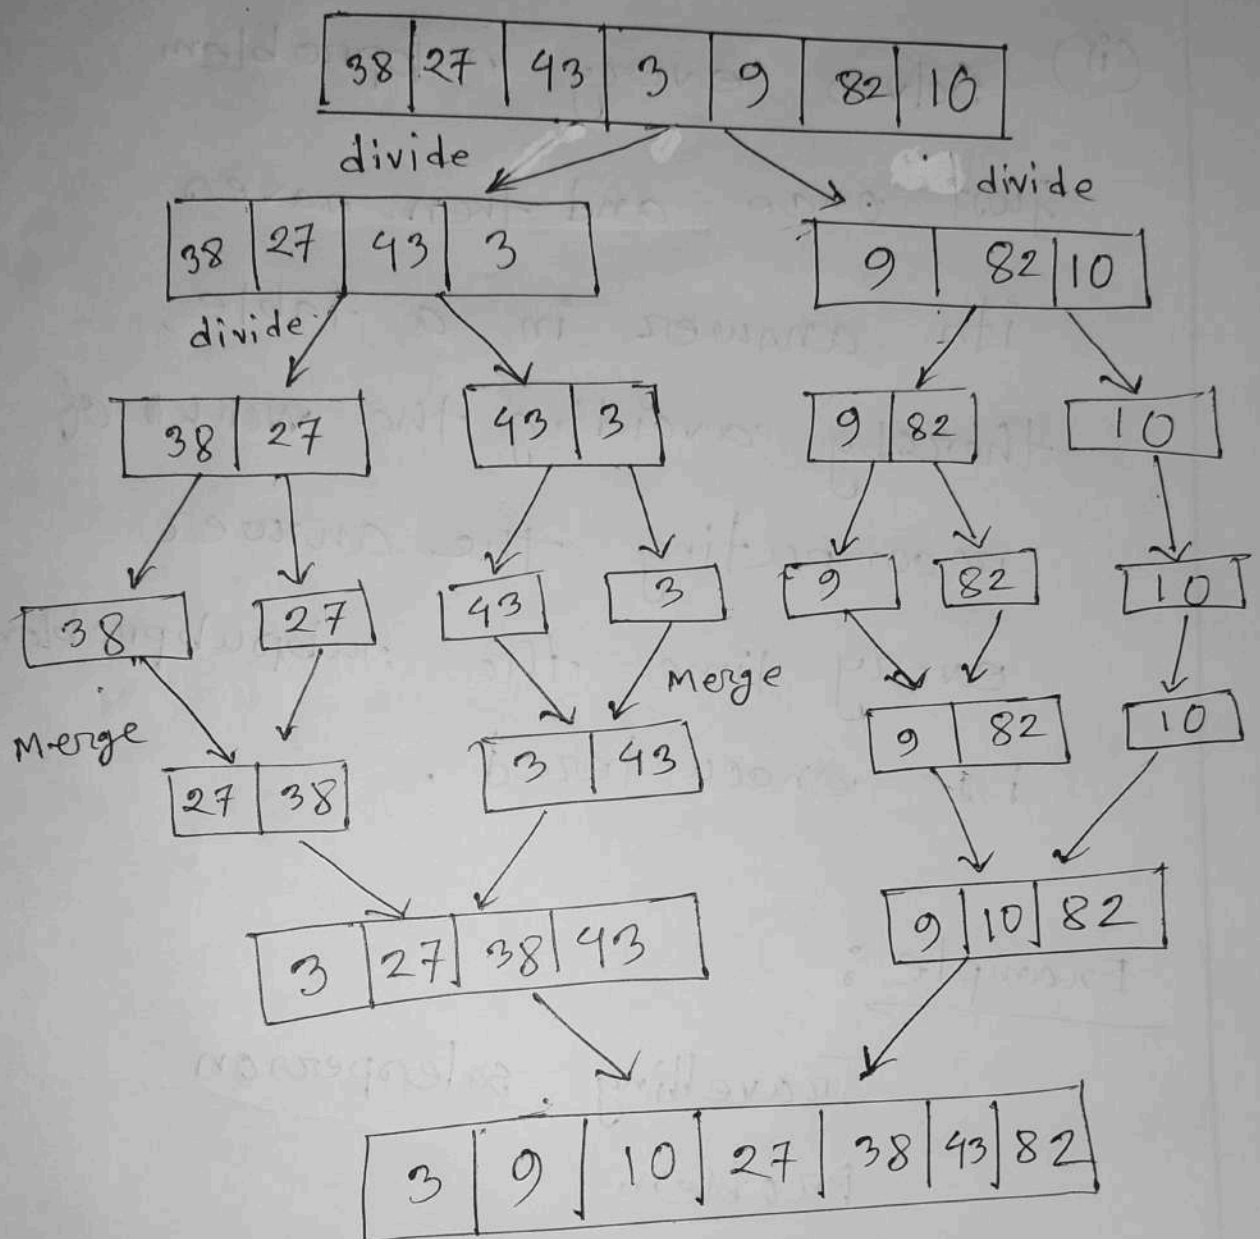

Divide and Conquer

• Partition the problem into independent subproblems, solve the subproblems recursively, and then combine their solutions to solve the original problem

Example :

Merge sort

P.T.O

Dynamic approach:

(i), Applicable when the subproblems are not independent, that is, when subproblems share subproblems.

(ii) Solves every subproblem just once and then saves its answer in a table, thereby avoiding the work of recomputing the answer every time the subproblem is encountered.

Example :

Travelling salesperson
Problem

0	2	3
5	0	9
6	13	0

$$g(2, \emptyset) = c_{21} = 5$$

$$g(3, \emptyset) = c_{31} = 6$$

$$\begin{aligned} g(2, \{3\}) &= c_{23} + g(3, \{\emptyset\}) \\ &= (9 + 6) = 15 \end{aligned}$$

$$\begin{aligned} g(3, \{2\}) &= c_{32} + g(2, \{\emptyset\}) \\ &= (13 + 5) = 18 \end{aligned}$$

$$\begin{aligned} g(1, \{2, 3\}) &= \min \{ c_{12} + g(2, \{3\}), \\ &\quad c_{13} + g(3, \{2\}) \} \\ &= \min \{ (2 + 15), (3 + 18) \} \\ &= 17 \end{aligned}$$

path : $1 \rightarrow 2 \rightarrow 3 \rightarrow 1$

cost : 17

(Ans.)

Am. the. Q. No: 2

$\xrightarrow{\quad 0 \quad}$
(c)

Matrix-chain-ORDER(P)

$n \leftarrow \text{length}[P] - 1$

for $i \leftarrow 1$ to n do

$m[i, i] \leftarrow 0$

for $l \leftarrow 2$ to n do

for $i \leftarrow 1$ to $n - l + 1$ do

$j \leftarrow i + l - 1$

$m[i, j] \leftarrow \infty$

for $k \leftarrow i$ to $j - 1$ do

$q \leftarrow m[i, k] + m[k+1, j] +$

$P_{i-1} P_k P_j$

P.T.O

if $q < m[i, j]$ then

~~$m[i, j]$ then~~

$m[i, j] \leftarrow q$

$s[i, j] \leftarrow k$

return m and s

Am. the. Q. No: 2

(d)

This algorithm searches for the local optima and optimizes the local best solution to find the global optima. It begins by sorting all the edges and then selects the edge with the minimum cost. It continuously selects the best next choices given a condition that no loops are formed. The complexity of the greedy algorithm is $O(N^2 \log_2 N)$ and there is no guarantee that a global optimum solution is found.
